1.0 INTRODUCTION

Since 1979, PacifiCorp biologists, along with various state and federal agencies, have conducted annual surveys to estimate spawning escapement of kokanee in Cougar Creek, a tributary to Yale Reservoir. This report presents results of kokanee spawner surveys conducted on Cougar Creek and the Constructed Channel within the Swift Bypass Reach in 2017. Surveys are performed per Article 402(b) of the Yale and Swift Federal Energy Regulatory Commission (FERC) operating licenses and Article 402(c) of the Merwin FERC operating license.

2.0 STUDY AREA

Surveys for kokanee spawners were performed on Cougar Creek and the Constructed Channel in 2017. Cougar Creek is a third order stream and tributary to Yale Reservoir in Southwest Washington. The creek pours directly from an underground lava tube for approximately 1,700 meters before flowing into Yale Reservoir.

The Constructed Channel flows from a valve off of the Swift Power Canal for approximately 200 meters before entering the Lewis River channel within the Swift Bypass Reach. The valve that controls flow into the Constructed Channel is set to a level to contribute a constant flow of 14 cubic feet per second (cfs) (*Figure 1*).

Figure 1. Survey area map.

3.0 METHODS

To enumerate kokanee spawners two biologists, one on each side of the stream, walked together from the stream mouth upstream to its anadromous fish barrier. Each biologist counts spawning and holding kokanee on his/her side of the stream, including side-channels. This process is repeated on three to four occasions over the course of the kokanee spawn time-frame, mid-September through early-November, in order to garner a count at the peak of the spawning run. The highest count during the survey period is considered the peak, and is preceded and followed by surveys with a lower kokanee count.

4.0 RESULTS

Cougar Creek

Peak kokanee escapement estimates increased from 2016 (3,634) to 2017 (7,429). The 2017 spawning estimate of 7,429 fish (*Figure 2*) is the fourth lowest count on record (1978-2017).

As in previous years, Cougar Creek was surveyed on foot with two surveyors. Kokanee were enumerated from the stream mouth upstream to its origin, a distance of approximately 1,700 meters. For survey purposes, the accessible anadromous fish habitat in Cougar Creek is broken into five survey reaches. There are a series of three major log jams in Reach 2 and 3 of Cougar Creek. In 2017, the upper extent of kokanee spawning was observed to be just

above the first log jam in Reach 3 which is the second of the three major log jams encountered.

Cougar Creek was surveyed for kokanee four times in 2017 (*Table 1*). Survey conditions during the sampling time period (Sep – Nov) were ideal prior to the third week of October, at which time heavy rainfall visited the area and made surveys difficult due to high water. However, even with the higher stream flows, water clarity during each survey was ideal.

4.1 Distribution and Timing

The peak kokanee count was recorded on October 17, 2017 (*Table 1*). This peak timing of kokanee abundance in 2017 is typical and within historical timeframes on record (1978-2017). Most kokanee were observed in Reach 2, which is consistent with prior years. This largest concentration of kokanee occurs just below the first log jam encountered on their travel upstream.

Table 1. Distribution and peak counts of kokanee in Cougar Creek in 2017

* Estimate uses a 2.3 multiplier of the peak count (Graves unpublished data, 1982)

Reach	Kokanee Escapement Recruiting to Cougar Creek 2016			
	9/18	9/26	10/17	10/30
1	60	300	1,500	440
2	30	50	1,730	1810
3	0	0	0	290
4	0	0	0	0
5	0	0	0	0
<i>Spawning Estimate</i>	207	805	7,429	5,842

4.2 Escapement

The kokanee spawning escapement in 2017 is estimated at 7,429 fish (*Figure 2*). This is the fourth lowest spawner count on record, though an increase from the peak observed in 2016 (3,634). Kokanee escapement into Cougar Creek has been less than the historical running average of 72,263 since 2006 (*Table 3*). This year’s estimate is also well below the ten-year average of 24,519 fish.

Figure 2. Kokanee spawning estimates for Cougar Creek, 1978-2017

4.3 Length Distribution

Due to low escapement numbers and high flows, kokanee carcasses were difficult to find in 2017, therefore lengths were only measured from 10 male and 10 female kokanee (*Figure 3*). Lengths came from both Cougar Creek and Constructed Channel kokanee. Lengths of kokanee in both reaches were similar to each other in 2017, and due to the low numbers of recovered carcasses, were pooled. The average lengths of male and female kokanee in 2017 were 318 and 316 millimeters, respectively.

Combined mean fork length of all kokanee observed in 2017 (317 millimeters) was smaller than what was observed during 2016 (323 millimeters). Historically, mean fork length is a general indicator of number of spawners. The larger the fish, the less spawners observed; conversely, the smaller the mean fork length of spawners, the higher the spawner escapement.

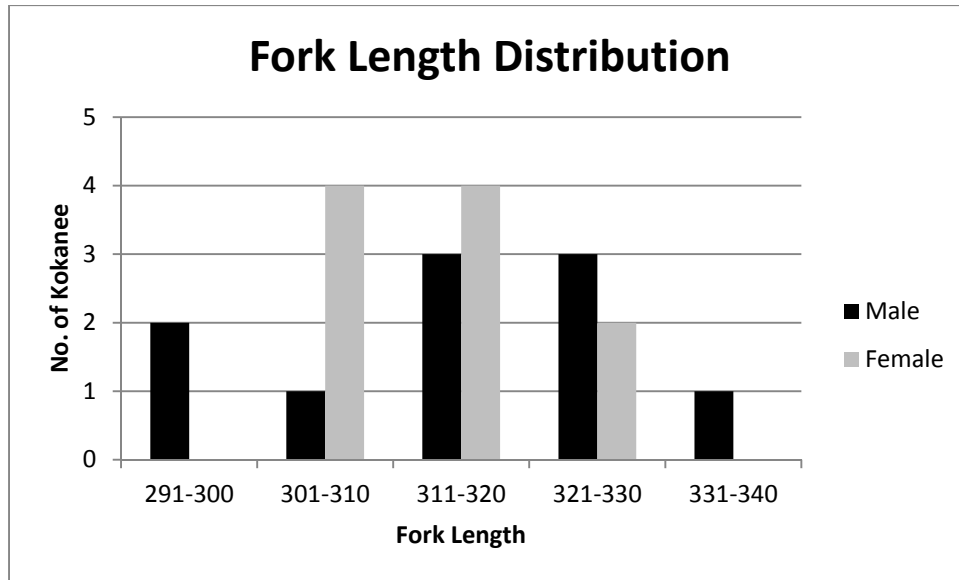

Figure 3. Length frequency histogram of male (n=10) and female (n=10) kokanee lengths (FL) sampled in Cougar Creek and the Constructed Channel, Washington – 2017

The average length of this year’s female kokanee (316 mm) was approximate to the average female length observed in 2016 (315 mm). The average female fork length in 2017 is greater than the historical running average of 288 millimeters (1978-2017).

With the regression line established in *Figure 4*, the average fork length size for females in 2017 is under-estimated from the equation by two percent. The fitted line suggests that given the spawning population estimate the female average length should be 311 millimeters, instead of the observed average of 316 millimeters, an underestimate of 5 millimeters. This observed difference in estimation of two percent is negligible and may indicate that during the reservoir life-cycle of this brood year that productivity was ideal for proper fish growth and development for this brood escapement estimation.

The size at spawning estimate may be a good indication of reservoir production in terms of food availability and fish growth. When kokanee are smaller than anticipated (based on size at spawning and spawning escapement) it may be an indication that reservoir productivity was limited at some point during their residency in Yale Reservoir.

Figure 4. Relationship between mean kokanee fork length (female) and spawning escapement in Cougar Creek (1978-2017). Red dot represents 2017.

4.4 Constructed Channel

One Constructed Channel kokanee spawner survey was completed on October 24, 2017 from its confluence with the Swift Bypass Reach upstream to its anadromous fish barrier, a distance of approximately 200 meters. A peak count of 1,190 kokanee spawners was recorded, this compares to a peak count of 890 kokanee spawners recorded in 2016 (Table 2). Fork length measurements from two male kokanee were also recorded and combined with the Cougar Creek data for an overall kokanee spawner length analysis.

The escapement estimate in 2017 (2,553) is very similar to what was estimated in 2016 (2,047) (Table 2). It is important to note that the flows within the Constructed Channel come straight off the Swift Power Canal via a mechanically controlled stem valve that is set to release a constant 14 cfs. Habitat improvements to the Constructed Channel were completed by PacifiCorp in 2010, and the constant flow rate of 14 cfs has been in effect since that time.

Table 2. Historical Constructed Channel peak counts and estimated spawning escapement.

Constructed Channel		
Year	Peak Count	Estimated Spawning Escapement
2010	410	943
2011	500	1,150
2012	3,400	7,820
2013	450	1,035
2014	450	1,035
2016	890	2,047
2017	1,190	2,553
